## 6 Radiative corrections

### 6.1 Optical theorem

We have seen in Advanced Quantum Theory that tree diagrams are in general real. So there is no imaginary parts. Need to restore perturbatively in higher-order corrections. Then the optical theorem is valid again.

S-matrix is unitary:  $S^\dagger S = \mathbb{1}$  with  $S = \mathbb{1} + iT$ . Thus

$$-i(T - T^\dagger) = T^\dagger T$$

We take matrix element for  $k_1 k_2 \rightarrow p_1 p_2$  scattering. On RHS, insert a complete set of states,

$$\langle p_1 p_2 | T^\dagger T | k_1 k_2 \rangle = \sum_n \prod_{i=1}^n \int \frac{d^3 q_i}{(2\pi)^3 2E_i} \langle p_1 p_2 | T^\dagger | q_1 \dots q_n \rangle \langle q_1 \dots q_n | T | k_1 k_2 \rangle$$

Reduce  $T_{fi} = (2\pi)^4 \delta^{(4)}(p_f - p_i) M_{fi}$  and omitting overall  $(2\pi)^4 \delta^{(4)}(p_f - p_i)$

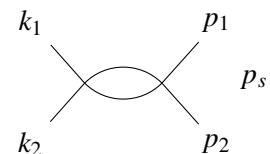

$$\begin{aligned} & -i [\mathcal{M}(k_1 k_2 \rightarrow p_1 p_2) - \mathcal{M}^*(p_1 p_2 \rightarrow k_1 k_2)] \\ &= \underbrace{\sum_n \prod_{i=1}^n \int \frac{d^3 q_i}{(2\pi)^3 2E_i}}_{\text{invariant phase-space volume element}} \mathcal{M}^*(p_1 p_2 \rightarrow q_1 \dots q_n) \mathcal{M}(k_1 k_2 \rightarrow q_1 \dots q_n) (2\pi)^4 \delta^{(4)}(k_1 + k_2 - \sum_i q_i) \end{aligned}$$

So optical theorem, for forward scattering ( $p_1 = k_1, p_2 = k_2$ ) reads (see 4.5.1)

$$\text{Im } \mathcal{M}(k_1 k_2 \rightarrow k_1 k_2) = 2F \sigma_{\text{tot}}(k_1 k_2 \rightarrow \text{anything})$$

$$2\sqrt{s} |f_i^{\text{CMS}}| = \lambda^{\frac{1}{2}}(s, m_1^2, m_2^2)$$

**Optical theorem for Feynman diagrams** Consider a specific diagram contributing to the imaginary part, e.g. in  $\phi^4$ -theory.

$$i\mathcal{M}(s) = \frac{\lambda^2}{2} \int \frac{d^4 q}{(2\pi)^4} \frac{1}{[(p_s/2 - q)^2 - M^2 + i\epsilon][(p_s/2 + q)^2 - M^2 + i\epsilon]} \quad (6.1.1)$$

From optical theorem:  $\text{Im } \mathcal{M}(s < 4M^2) = 0$ , so  $\mathcal{M}(s < 4M^2) \in \mathbb{R}$ , (Since it is physical case, the cross section must vanish) when regarding  $\mathcal{M}(s)$  as an analytic function of  $s$  beyond what physical S-matrix element allow.

**Schwarz reflection principle** If (in some region) analytic function  $\mathcal{M}(s)$  is real at least for a finite, nonvanishing interval  $\in \mathbb{R}$ , then

$$\mathcal{M}(s^*) = \mathcal{M}^*(s) \quad (6.1.2)$$

Hence

$$\mathcal{M}(s + i\epsilon) - \mathcal{M}(s - i\epsilon) \equiv \text{disc} \mathcal{M}(s) = \mathcal{M}(s + i\epsilon) - \mathcal{M}^*(s + i\epsilon) = 2i \text{Im} \mathcal{M}(s + i\epsilon)$$

Onset of imaginary part for  $s \leq 4M^2$  necessarily leads to a "branch cut", a nontrivial discontinuity in the complex energy plane. The branch cut is equivalent to  $\sqrt{4M^2 - s}$ . Function has discontinuity, a cut, on real axis.

How can we calculate the discontinuity (= imaginary part) of the above diagram?

Use centre-of-mass system  $p_s = (\sqrt{s}, \mathbf{0})$ . Poles from propagators

$$\begin{aligned} \frac{s}{4} \mp \sqrt{s}q^0 + q^2 - M^2 + i\epsilon &= 0 \\ \Leftrightarrow (q^0)^2 \pm \sqrt{s}q^0 + \frac{s}{4} - |\mathbf{q}|^2 - M^2 + i\epsilon &= 0 \end{aligned}$$

first propagator	$q^0 = +\frac{\sqrt{s}}{2} \pm (\sqrt{M^2 +  \mathbf{q} ^2} - i\epsilon) = +\frac{\sqrt{s}}{2} \pm (E_q - i\epsilon)$
second propagator	$q^0 = -\frac{\sqrt{s}}{2} \pm (E_q - i\epsilon)$

If we close the contour of the  $q_0$  integration in the lower half plane, we only pick up the 2 residues at  $\mp \frac{\sqrt{s}}{2} + E_q - i\epsilon$ . As  $E_q$  is positive, only  $-\frac{\sqrt{s}}{2} + E_q - i\epsilon$  from second propagator contributes to discontinuity.

So pinching up the residue equivalent to replacement under  $q^0$  integration

$$\frac{1}{(p_s/2 + q)^2 - M^2 + i\epsilon} \mapsto \underbrace{-2\pi i}_{\text{orientation of contour}} \delta((p_s/2 + q)^2 - M^2)$$

Determine the residue of the rest at the pole at  $-\frac{\sqrt{s}}{2} + E_q - i\epsilon$

$$M(s) \mapsto -\frac{\lambda^2}{2} \int \frac{d^3 q}{(2\pi)^3} \frac{1}{2E_q \sqrt{s}(\sqrt{s} - 2E_q)}$$

With no angular dependence and using substitution (note the limits of integral also change)  $d^3 q \rightarrow 4\pi|q|^2 d|q| = 4\pi|q|E_q dE_q$

$$= -\frac{\lambda^2}{8\pi^2} \int_M^\infty \frac{dE_q \sqrt{E_q^2 - M^2}}{\sqrt{s}(\sqrt{s} - 2E_q)} \quad (6.1.3)$$

It has pole at  $E_q = \frac{\sqrt{s}}{2}$ . The second pole in 6.1.1 at  $\frac{\sqrt{s}}{2} + E_q - i\epsilon$  would produce a pole in 6.1.3 for  $E_q = -\frac{\sqrt{s}}{2}$ , outside the integration range  $M \leq E_q < \infty$ .

- for  $\sqrt{s} < 2M$ , 6.1.3 is manifestly real.
- for  $\sqrt{s} > 2M$ , the pole at  $E_q = \frac{\sqrt{s}}{2}$  in 6.1.3 contributes differently depending on  $\sqrt{s} \pm i\epsilon$ ; difference yields discontinuity.

Use

$$\frac{1}{\sqrt{s} - 2E_q \pm i\epsilon} = \underbrace{\frac{P}{\sqrt{s} - 2E_q}}_{\text{real}} \underbrace{\mp i\pi \delta(\sqrt{s} - 2E_q)}_{\text{yields discontinuity}}$$

So for calculation of the discontinuity, have replacement

$$\frac{1}{(p_s/2 - q)^2 - M^2 + i\epsilon} \mapsto -2\pi i \delta((p_s/2 - q)^2 - M^2)$$

for other propagator too!

**Cuthosky rules (1960)** replace cut propagator according to

$$\frac{1}{p^2 - M^2 + i\epsilon} \mapsto -2\pi i \delta(p^2 - M^2) \quad (6.1.4)$$

to calculate discontinuity across the cut!

Calculation completed:

$$\text{disc} \left( \text{diagram} \right) = i \frac{\lambda^2}{2} \int \frac{d^4 q}{(2\pi)^4} 2\pi \delta(q^2 - M^2) 2\pi \delta((p_s - q)^2 - M^2)$$

$$\begin{aligned}
& \text{using } d^4q = dq^0 dq |q|^2 d\Omega_q \text{ and } (p_s - q)^2 - M^2 = s - 2\sqrt{s}q^0 \\
&= \frac{\lambda^2}{2} \frac{i}{4\pi^2} \int \frac{|q|^2 dq |d\Omega_q|}{2q^0} \delta(s - 2\sqrt{s}q^0) \\
&= \frac{\lambda^2}{2} \frac{i}{8\pi^2} \int \sqrt{(q^0)^0 - M^2} dq^0 d\Omega_q \delta(s - 2\sqrt{s}q^0) \\
&= \frac{\lambda^2}{2} \frac{i}{8\pi^2} \frac{\sqrt{s/4 - M^2}}{2\sqrt{s}} \int d\Omega_q \\
&= \frac{\lambda^2}{2} \frac{i}{8\pi} \sqrt{1 - \frac{4M^2}{s}} \\
&\text{Im}\mathcal{M} = \frac{\lambda^2}{4} \frac{1}{8\pi} \sqrt{1 - \frac{4M^2}{s}}
\end{aligned}$$

Note  $\sigma = \frac{\lambda^2}{32\pi}$  and  $2F = s \sqrt{1 - \frac{4M^2}{s}}$ . Thus optical theorem is still valid.

We can do more. Construct the complete  $\mathcal{M}(s)$  from  $\text{Im } \mathcal{M}(s)$  through a dispersion relation!

Use Cauchy's theorem:

$$\mathcal{M}(s) = \frac{1}{2\pi i} \oint \frac{\mathcal{M}(z)dz}{z-s} \quad (6.1.5)$$

dropping the large circle

$$\begin{aligned}
&\mapsto \frac{1}{2\pi i} \int_{C_+ + C_-} \frac{\mathcal{M}(z)dz}{z-s} \\
&= \frac{1}{2\pi i} \left[ \int_{4M^2}^{\infty} \frac{\mathcal{M}(z+i\epsilon)dz}{z-s} - \int_{4M^2}^{\infty} \frac{\mathcal{M}(z-i\epsilon)dz}{z-s} \right] \\
&= \frac{1}{2\pi i} \int_{4M^2}^{\infty} \frac{\text{disc}\mathcal{M}(z)dz}{z-s} \\
&= \frac{1}{\pi} \int_{4M^2}^{\infty} \frac{\text{Im } \mathcal{M}(z)dz}{z-s} \quad (6.1.6)
\end{aligned}$$

Repeat the exercise for  $\frac{\mathcal{M}(s)-\mathcal{M}(0)}{s}$  (no pole introduced!).

$$\begin{aligned}\operatorname{Im}\left(\frac{\mathcal{M}(s)-\mathcal{M}(0)}{s}\right) &= \frac{\operatorname{Im}\mathcal{M}(s)}{s} \\ \mathcal{M}(s)-\mathcal{M}(0) &= \frac{s}{\pi} \int_{4M^2}^{\infty} \frac{\operatorname{Im}\mathcal{M}(z)dz}{z(z-s)} \\ &= \frac{\lambda^2}{2} \frac{s}{(4\pi)^2} \int_{4M^2}^{\infty} \frac{dz}{z(z-s)} \sqrt{1-\frac{4M^2}{z}}\end{aligned}$$

using  $\sigma = \sqrt{1-\frac{4M^2}{s}}$  and  $\zeta = \sqrt{1-\frac{4M^2}{z}}$

$$\begin{aligned}&= \frac{\lambda^2}{2} \frac{1}{8\pi^2} \int_0^1 \frac{\zeta^2}{\zeta^2-\sigma^2} d\zeta \\ &= \frac{\lambda^2}{2} \begin{cases} \frac{1}{8\pi^2} \left(1 - \frac{\sigma}{2} \log \frac{\sigma+1}{\sigma-1}\right) & s < 0 \Leftrightarrow \sigma > 1 \\ \frac{1}{8\pi^2} \left(1 - \sqrt{-\sigma^2} \arctan \frac{1}{\sqrt{-\sigma^2}}\right) & 0 < s < 4M^2, \sigma^2 < 0 \\ \frac{1}{8\pi^2} \left(1 - \frac{\sigma}{2} \log \frac{1+\sigma}{1-\sigma} + \frac{i\sigma}{16\pi}\right) & s > M^2, 0 < \sigma < 1 \end{cases}\end{aligned}$$

Note: we are going to calculate this diagram again, noticing that  $\int \frac{d^4q}{(q^2 \dots)(q^2 \dots)}$  is logarithmically divergent!. The above representation demonstrates that this divergence resides in  $\mathcal{M}(0)$ !

## 6.2 Field-strength renomrlization

What is structure of the propagator  $\langle \Omega | T \phi(x) \phi(y) | \Omega \rangle$  at higher orders? At lower order

$$\text{---} \overrightarrow{p} \text{---} = \frac{i}{p^2 - M^2 + i\epsilon}$$

Beyond this the propagator is not a simple pole. In  $\phi^3$ -theory  branch cuts are at

$p^2 \leq 4M^2$ . In  $\phi^4$ -theory  branch cuts are at  $p^2 \leq 9M^2$ . To induce cuts in the analytic structure.

Insert complete set of intermediate states ( $x^0 > y^0$ )

$$\langle \Omega | T \phi(x) \phi(y) | \Omega \rangle = \sum_{\lambda} \int \frac{d^3p}{(2\pi)^3 2E_p(\lambda)} \langle \Omega | \phi(x) | \lambda_{\mathbf{p}} \rangle \langle \lambda_{\mathbf{p}} | \phi(y) | \Omega \rangle$$

with

$\lambda$  multiparticle state

$\lambda_0$  "rest frame", i.e.  $\hat{\mathbf{P}} |\lambda_0\rangle = 0$

$\lambda_{\mathbf{p}}$  boosted to momentum  $\mathbf{p}$

Call energy of  $\lambda_0 = m_{\lambda}$ . From single particle to multi particle  $E_{\mathbf{p}}(\lambda) = \sqrt{m_{\lambda}^2 + |\mathbf{p}|^2}$ .

$$\begin{aligned}\langle \Omega | \phi(x) | \lambda_p \rangle &= \langle \Omega | e^{i\hat{P}x} \phi(0) e^{-i\hat{P}x} | \lambda_p \rangle \\ &= \langle \Omega | \phi(0) | \lambda_p \rangle e^{-ipx} \Big|_{p^0=E_p}\end{aligned}$$

$\Omega$  and  $\phi(0)$  are invariant under momentum boost

$$= \langle \Omega | \phi(0) | \lambda_0 \rangle e^{-ipx} \Big|_{p^0=E_p}$$

$$\langle \Omega | T \phi(x) \phi(y) | \Omega \rangle = \sum_{\lambda} \int \frac{d^3 p}{(2\pi)^3 2E_p(\lambda)} e^{-ip(x-y)} |\langle \Omega | \phi(0) | \lambda_0 \rangle|^2 \quad (6.2.1)$$

$$= \sum_{\lambda} \int \frac{d^4 p}{(2\pi)^4} \underbrace{\frac{i}{p^2 - m_{\lambda}^2 + i\epsilon} e^{-ip(x-y)}}_{D_F(x-y; m_{\lambda}^2) \text{ when combined with } y^0 > x^0} |\langle \Omega | \phi(0) | \lambda_0 \rangle|^2 \quad (6.2.2)$$

$$(6.2.3)$$

Formally write this as

$$\langle \Omega | T \phi(x) \phi(y) | \Omega \rangle = \int_0^{\infty} \frac{ds}{2\pi} \rho(s) D_F(x-y; s) \quad (6.2.4)$$

with  $\rho(s)$  the spectral density function.

$$\rho(s) := \sum_{\lambda} (2\pi) \delta(s - m_{\lambda}^2) |\langle \Omega | \phi(0) | \lambda_0 \rangle|^2 \quad (6.2.5)$$

A typical spectral function looks like

Figure 6.1: typical spectral function

Single particle contribution

$$\rho(s) = 2\pi \delta(s - m^2) Z + (\text{contributions } \geq 4m^2) \quad (6.2.6)$$

with  $Z = |\langle \Omega | \phi(0) | \lambda_0 \rangle|^2$  the field-strength renormalization factor.

Fourier transforming two-point function

$$\begin{aligned} & \int d^4x e^{ipx} \langle \Omega | T \phi(x) \phi(0) | \Omega \rangle \\ &= \int_0^\infty \frac{ds}{2\pi} \rho(s) \frac{i}{p^2 - s + i\epsilon} \\ &= \frac{iZ}{p^2 - m_i^2 \epsilon} + \int_{\sim 4m^2}^\infty \frac{ds}{2\pi} \rho(s) \frac{i}{p^2 - s + i\epsilon} \end{aligned}$$

Comparing to free theory:  $\langle 0 | \phi(0) | p \rangle = 1$  hence  $Z = 1$ .

## 6.3 LSZ reduction formula

## 6.4 The propagator(again)

See also Peskin & S. Chapter 10.2.

How do we calculate the propagator and the wave-function renormalization factor  $Z$  in perturbation theory, using Feynman diagrams? Call mass parameter in  $\mathcal{L} = \frac{1}{2}(\partial_\mu \phi_0)^2 - \frac{m_0^2}{2}\phi_0^2 - \frac{\lambda_0}{4!}\phi_0^4$   $m_0$  bare mass.

In  $\phi^4$ -theory "1-particle-irreducible" (1PI) contribution is

$$-i\Sigma(p^2) = \text{---}\bigcirc\text{---} + \text{---}\bigcirc\!\!\!\bigcirc\text{---} + \text{---}\bigcirc\text{---} + \dots$$

Then the complete propagator using  $D_F^0(p^2) = \frac{i}{p^2 - m_0^2 + i\epsilon}$  is

$$\begin{aligned} D_F(p^2) &= \text{---}\text{---} + \text{---}\bigcirc(-i\Sigma)\text{---} + \text{---}\bigcirc(-i\Sigma)\bigcirc(-i\Sigma)\text{---} \\ &= D_F^0(p^2) + D_F^0(p^2)(-i\Sigma(p^2))D_F^0(p^2) + D_F^0(p^2)(-i\Sigma(p^2))D_F^0(p^2)(-i\Sigma(p^2))D_F^0(p^2) \end{aligned}$$

It is clearly a geometric series

$$= \frac{D_F^0(p^2)}{1 + i\Sigma(p^2)D_F^0(p^2)} = \frac{i}{p^2 - m_0^2 - \Sigma(p^2)}$$

The pole of propagator does not occur at  $m_0^2$  anymore. It will be shifted by  $\Sigma \sim \mathcal{O}(\lambda)$ !

Choose  $m^2$  by the condition

$$m_0^2 + \Sigma(m^2) = m^2 \quad (6.4.1)$$

Expand

$$\Sigma(p^2) = \Sigma(m^2) + (p^2 - m^2)\Sigma'(m^2) + (p^2 - m^2)\tilde{\Sigma}(p^2) \quad (6.4.2)$$

where  $\tilde{\Sigma}$  represents a correction (to first order Taylor expansion) and it satisfies  $\tilde{\Sigma}(m^2) = 0$ .

Then the propagator

$$D_F(p^2) = \frac{i}{p^2 - m_0^2 - \Sigma(p^2)} = \frac{i}{(p^2 - m^2)(1 + \frac{\Sigma(m^2) - \Sigma(p^2)}{p^2 - m^2})}$$

using 6.4.2

$$\begin{aligned}
 &= \frac{i}{(p^2 - m^2)(1 - \Sigma'(m^2) - \tilde{\Sigma}(p^2))} \\
 &= \frac{iZ}{p^2 - m^2} \cdot \frac{1}{1 - Z\tilde{\Sigma}(p^2)} \\
 &= \frac{iZ}{p^2 - m^2} + \text{regular}
 \end{aligned} \tag{6.4.3}$$

with  $Z = \left(1 - \frac{\partial}{\partial p^2} \Sigma(p^2)\big|_{p^2=m^2}\right)^{-1}$

Starting point Lagrangian is  $\mathcal{L} = \frac{1}{2}(\partial_\mu \phi_0)^2 - \frac{m_0^2}{2}\phi_0^2 - \frac{\lambda_0}{4!}\phi_0^4$ . To remove  $Z$  from numerator from the propagator and instead put  $\sqrt{Z}$  onto the couplings at each end. Since each internal vertex has 4 lines (remember the vertex carries the coupling constant)

$$\lambda_0 \mapsto \lambda_1 = Z^2 \lambda_0 \tag{6.4.4}$$

In  $\Sigma$  and  $\tilde{\Sigma}$ , there are 2 external lines without  $\sqrt{Z}$ , so

$$\Sigma(p^2, \lambda_0, \text{old } D_F) = \frac{1}{Z} \Sigma_1(p^2, \lambda_1, \text{new } D'_F) \tag{6.4.5}$$

(same expression for  $\tilde{\Sigma}$ ).

Thus we get the new propagator

$$D'_F(p^2) = \frac{i}{p^2 - m^2} \cdot \frac{1}{1 - \tilde{\Sigma}_1(p^2)} \tag{6.4.6}$$

where  $\tilde{\Sigma}_1(m^2) = 0$ .

Define the renomalized field

$$Z^{-\frac{1}{2}}\phi_0 = \phi \tag{6.4.7}$$

Then  $D'_F$  is the Fourier transform of  $\langle 0|T\phi(x)\phi(y)|0\rangle$

Rewrite the Lagrangian as

$$\mathcal{L} = \frac{1}{2}((\partial_\mu \phi)^2 - m^2 \phi^2) - \underbrace{\left[ \frac{\lambda_1}{4!}\phi^4 - \frac{1}{2}\delta m^2 \phi^2 + \frac{1}{2}(Z-1)((\partial_\mu \phi)^2 - m^2 \phi^2) \right]}_{\text{counter-terms}} \tag{6.4.8}$$

where  $\delta m^2 = -Z(m^2 + m_0^2) = -Z\Sigma(m^2) = -\Sigma_1(m^2)$ . Everythin inside the box can be considered as "interaction". May look weird given the kinetic/mass-like terms, but no contradiction. Consider just  $\mathcal{L} = \frac{1}{2}(\partial\phi)^2 - \frac{m^2}{2}\phi^2$ . The mass-term  $\equiv$  "interaction".

A massless propagator  $\text{---}\frac{i}{p^2}\text{---}$  and interaction  $\text{---}\times\text{---} = -im^2$ . The resummed propagator is then

$$\begin{aligned}
 \text{---}\text{---}\text{---} &= \text{---}\text{---}\text{---} + \text{---}\times\text{---} + \text{---}\times\times\text{---} + \dots \\
 &= \frac{i}{p^2} \left( 1 + \frac{i}{p^2} \cdot (-im^2) + \dots \right) \\
 &= \frac{i}{p^2} \left( 1 - (-im^2) \frac{i}{p^2} \right)^{-1} = \frac{i}{p^2 - m^2}
 \end{aligned}$$

Actually this is not all. We will also have to further renormalize  $\lambda_1$

$$\begin{aligned}
 &= \frac{\mu^{2(4-d)} \lambda^2}{2} \int_0^1 dx \int \frac{d^d k}{(2\pi)^d} \frac{1}{[k^2 - \Delta(x)]^2} \\
 &= \frac{\lambda^2}{2} \mu^{2(4-d)} \int_0^1 dx \frac{1}{(4\pi)^{d/2}} \frac{\Gamma(2-d/2)}{\Gamma(2)} \frac{1}{\Delta(x)(2-d/2)} \\
 &= \frac{\lambda^2}{2} \frac{\mu^{4-d}}{(4\pi)^2} \left\{ -2 \left[ \frac{1}{d-4} + \frac{1}{2} (\gamma_E - \log 4\pi + \log \left( \frac{M}{\mu} \right)) \right] - \int_0^1 dx \log \frac{\Delta(x)}{M^2} \right\} \quad \Delta(x) = M^2 - x(1-x)p^2 \\
 &\int_0^1 dx \log \frac{M^2 - x(1-x)p^2}{M^2} = \int_0^1 dx \log \left[ \left( \frac{\sigma+1}{2} - x \right) \left( x + \frac{\sigma-1}{2} \right) \right] - \log \frac{\sigma^2 - 1}{4}, \quad \sigma = \sqrt{1 - \frac{4M^2}{p^2}} \\
 &= \sigma \log \frac{\sigma+1}{\sigma-1} - 2
 \end{aligned}$$

Valid for  $p^2 < 0$ , rest by analytic continuation

Compare  $M(s) - M(0)$  calculated based on Cutkosky and dispersion integral. Easier

$$\begin{aligned}
 M(0) &= \frac{1}{i} \int \frac{d^d k}{(2\pi)^d} \frac{1}{(k^2 - M^2)^2} = \frac{\partial}{\partial M^2} \frac{1}{i} \int \frac{d^d k}{(2\pi)^d} \frac{1}{k^2 - M^2} \\
 &= \frac{\partial}{\partial M^2} \left\{ -\frac{M^2}{8\pi^2} \left[ \frac{1}{d-4} + \frac{1}{2} (\gamma_E - 1 - \log 4\pi) + \frac{1}{2} \log \frac{M^2}{\mu^2} \right] \right\}
 \end{aligned}$$

1 cancelled by the derivative of log

$$= -\frac{1}{8\pi^2} \left[ \frac{1}{d-4} + \frac{1}{2} (\gamma_E - \log(4\pi)) + \frac{1}{2} \log \frac{M^2}{\mu^2} \right]$$

Lets summarise the renormalization of  $\phi^4$  at one loop

- is indeoendt of  $p^2$ ! Hence  $\Sigma(p^2)$  at  $O(\lambda)$  only renormalises the mass, there is no wavefunction renormalisation  $Z(\sim \frac{\partial \Sigma}{\partial p^2} |_{p^2=M^2})$ . Thus  $Z = 1 + O(\lambda^2)$  This does change at  $O(\lambda^2)$ :  $\rightarrow Z \neq 1$
- Mass renormalisation Then

$$\begin{aligned}
 M^2 &= M^2 + \frac{\lambda M^2}{16\pi^2} \left[ \frac{1}{d-4} + \frac{1}{2} (\gamma_E - 1 - \log 4\pi + \log \frac{M}{\mu}) \right] - M^2 + M^2 \\
 &= M_0^2 + \frac{\lambda M^2}{16\pi^2} \left[ \frac{1}{d-4} + \frac{1}{2} (\gamma_E - 1 - \log 4\pi + \log \frac{M}{\mu}) + O(\lambda, (d-4)) \right] \\
 M_{\text{physical}}^2 &\neq f(\mu), \quad \lambda \mu^{4-d} M^2 = \lambda_0 M_0^2 + O(\lambda^2) \text{ and } \lambda_0 \text{ and } M_0 \text{ are independent of } \mu
 \end{aligned}$$

- Coupling constant renormalisation. Lets choose renormalisation point for  $\lambda$  at  $s = t = u = 0$  for simplicity: with  $Z = 1$

$$\lambda_0 = \lambda \mu^{4-d} Z_\lambda = \lambda \mu^{4-d} \left\{ \underbrace{1 - \frac{3}{\lambda} 16\pi^2 \left[ \frac{1}{d-4} \right]}_{Z^{MS}_\lambda \text{ minimal subtraction}} + \frac{1}{2}(\gamma_E - \log 4\pi + \log \frac{M}{\mu}) + O \right\} \lambda^2$$

$$\lambda_0 = \lambda \mu^{4-d} Z_\lambda = \lambda \mu^{4-d} \left\{ \underbrace{1 - \frac{3}{\lambda} 16\pi^2 \left[ \frac{1}{d-4} \right] + \frac{1}{2}(\gamma_E - \log 4\pi + \log \frac{M}{\mu})}_{Z^{MS}_\lambda \text{ modified minimal subtraction}} + O \right\} \lambda^2$$

these two  $Z$  are mass-indepent

$$\lambda_0 = \lambda \mu^{4-d} Z_\lambda = \lambda \mu^{4-d} \left\{ \underbrace{1 - \frac{3}{\lambda} 16\pi^2 \left[ \frac{1}{d-4} \right] + \frac{1}{2}(\gamma_E - \log 4\pi + \log \frac{M}{\mu})}_{Z_{\lambda \text{ mass-dependent}}} + O \right\} \lambda^2$$

## 6.5 Superficial degree of divergence

How do we know that we are done renormalising the theory with

- wave function
- mass
- coupling

Can't there be more divergences?

Want to analyse superficial degree of divergence  $D$  of an arbitrary loop diagram with

- $d$  dimension
- $L$  number of loops
- $I$  number of internal propagators
- $E$  number of external lines
- $V$  number of vertices

Matrix element of an arbitrary diagram generically

$$\sim \lambda^V \int \frac{d^d k_1 d^d k_2 \dots d^d k_L}{(k_{i_1}^2 - M^2) \dots (k_{i_l}^2 - M^2)}$$

ro clearly

$$D = dL - 2I \quad (6.5.1)$$

$D \geq 0$  divergent ( $D = 0$  logarithmically divergent) and  $D < 0$  convergent.

Express  $L$  and  $I$  in terms of  $V$  and  $E$

•

$L$  = number of undetermined integrations

= number of propagators – number of momentum conservation at each vertex + 1 (because of overall momentum conservation)

$$L = I - V + 1 \quad (6.5.2)$$

- vertex linked to 4 legs, internal lines attached to 2 vertices, external line to 1

$$4V = 2I + E \quad (6.5.3)$$

solve 6.5.2 and 6.5.3 for  $L$  and  $I$

$$D = d + (d - 4)V - \left(\frac{d}{2} - 1\right)E \quad (6.5.4)$$

in physical 4 dimension

$$D = 4 - E \quad (6.5.5)$$

### Remarks

- for  $d = 4$ ,  $D$  is independent of  $V$ , only dependent on  $E$ .

- only a few small  $E$  produce  $D \geq 0$ , here (in  $\phi^4$ )  $E = 2$
- distinguish theories of different  $d$ 
  - $d < 4$ :  $D$  decreases with  $V$ , only finite number of diagrams (not n-point functions) diverges **super-renormalisable**
  - $d = 4$ :  $D$  is independent of  $V$ , only a finite number of amplitudes diverges, but at each order in perturbation theory **renormalisable**
  - $d > 4$ :  $D$  grows with  $V$ , even amplitude becomes divergent at some order in perturbation theory. **non-renormalisable**
- alternative characterisation in terms of mass dimension of coupling constant

$$\mathcal{L}_{\phi^4} = -\mu^{4-d} \frac{\lambda}{4!} \phi^4 = -\frac{\tilde{\lambda}}{4!} \phi^4$$

so  $[\tilde{\lambda}] = 4 - d$  in  $d$  dimension; hence

- $[\tilde{\lambda}] > 0$  super-renormalisable
- $[\tilde{\lambda}] = 0$  renormalisable

–  $[\tilde{\lambda}] < 0$  non-renormalisable

- why is this "superficial"? There can always be divergent subgraphs! These subgraphs are regularised and renormalised by the treatment of the "primitive divergences" we have already seen before.

**conclusion for  $\phi^4$**  the only primitive divergences are  $E = 2$  and  $E = 4$  (and  $E = 0$  the vacuum graphs) and we renormalise the theory by

$$M_0^2 = M^2 \left\{ 1 + c_m^{(1)} \frac{\lambda}{d-4} + c_m^{(2)} \frac{\lambda^2}{(d-4)^2} + \dots \right\} \quad (6.5.6)$$

$$\lambda_0 = \lambda \left\{ 1 + c_\lambda^{(1)} \frac{\lambda}{d-4} + c_\lambda^{(2)} \frac{\lambda^2}{(d-4)^2} + \dots \right\} \quad (6.5.7)$$

$$Z = 1 + c_z^{(2)} \frac{\lambda^2}{(d-4)^2} + \dots \quad (6.5.8)$$
